**ABSTRACT**

Methods and apparatus for crediting a media presentation device are disclosed. An example method includes obtaining ambient audio of a location including a media presentation device during a time period, detecting encoded information present in the ambient audio, crediting a first portion of the time period for the media presentation device to first media based on the encoded information, determining an on/off state of the media presentation device for a second portion of the time period different than the first portion based on the ambient audio, and crediting the second portion of the time period based on the on/off state of the media presentation device.

# METHODS AND APPARATUS FOR CREDITING A MEDIA PRESENTATION DEVICE

## FIELD OF THE DISCLOSURE

This patent claims priority to U.S. Provisional Patent Application No. 61/577,467, filed Dec. 19, 2011, the entirety of which is hereby incorporated by reference.

## FIELD OF THE DISCLOSURE

The present disclosure relates generally to audience measurement and, more particularly, to methods and apparatus for crediting a media presentation device.

## BACKGROUND

Media ratings and other audience metering information are typically generated by collecting media exposure information from a group of statistically selected households. Each of the statistically selected households, also called metered households, typically has a data logging and processing unit commonly referred to as a “home unit,” “meter” or “audience measurement device.” In metered households or, more generally, metering sites having multiple media presentation devices, the data logging and processing functionality may be distributed among a single home unit and multiple site units, where one site unit may be provided for each media presentation device or media presentation area and provides data to the home unit for processing and/or communicating to a central processing site. The home unit (or the combination of the home unit and the site units) includes sensors to gather data from the monitored media presentation devices (e.g., audio-video (AV) devices) at the selected site.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of an example media monitoring system constructed in accordance with the teachings of this disclosure to credit media presentation to a media presentation device.

FIG. 2 is a block diagram of an example audience measurement device in communication with an example media creditor as illustrated in FIG. 1.

FIG. 3 is a block diagram of another example audience measurement device in communication with another example media creditor as illustrated in FIG. 1.

FIG. 4 illustrates a time period representative of crediting media presentations and/or non-presentations to a media presentation device during in an example process to perform crediting.

FIG. 5 is a flowchart representative of example machine readable instructions that may be executed to implement the example audience measurement device of FIGS. 1-3.

FIG. 6 is a flowchart representative of example machine readable instructions that may be executed to implement the example media creditor of FIGS. 1-3.

FIG. 7 is a flowchart representative of example machine readable instructions that may be executed to implement the example media creditor and/or the example audience measurement device of FIGS. 1-3 to process captured audio.

FIG. 8 is a block diagram of an example processor system that may be used to execute the example machine readable

2

instructions of FIGS. 5-7 to implement the example audience measurement devices and/or the example media creditors of FIGS. 1-3.

## DETAILED DESCRIPTION

Certain examples are shown in the above-identified figures and described in detail below. In describing these examples, like or identical reference numbers are used to identify common or similar elements. Although the example systems and apparatus described herein include, among other components, software executed on hardware, such systems and apparatus is merely illustrative and should not be considered as limiting. Any or all of the disclosed components could be embodied exclusively in hardware, exclusively in software, exclusively in firmware or in some combination of hardware, firmware or software.

Metering data providing an accurate representation of the exposure to media content of persons in metered households is useful in generating media ratings of value to advertisers and/or producers of media content. Generating accurate metering data has become difficult as the media presentation devices have become more complex in functionality and interoperability.

Some existing methods for crediting metered environments with media exposure include connecting a metering device to a media presentation device (e.g., a television) in the metered environment and/or to sources of media (e.g., set top boxes, game consoles, etc.). Connecting and configuring the metering devices can be costly and time-consuming. Other existing methods include equipping each person in a metered environment with a personal meter to capture audio codes from ambient sounds. Personal meters are prone to being left in a different location than the associated person, and can result in inaccurate measurements. Still other existing methods include obtaining set top box data from multi-system operators, such as cable and/or satellite delivery systems. However, such information may be proprietary and/or may result in skewed data due to the differing characteristics of the customers of each type of delivery system. For example, customers of cable providers are statistically likely to watch different types of shows than customers of satellite providers. Extrapolating set top box data (or equivalent data) from multi-system operators to a general population may result in inaccurate measurements.

Furthermore, the previously-known technologies to detect the on state or the off state of a media presentation device, as discussed above, are complex to set up by a person without additional training (e.g., in locating the additional sensors properly to obtain a signal) and/or are expensive to build and/or transport (e.g., because additional components add cost and weight), which may reduce the number of participants capable of being included in a metering project. Acquiring data from other sources (e.g., purchasing set top box data from a multi-system operator) may be prohibitively expensive and/or statistically misrepresentative.

Against this backdrop, methods, apparatus, and articles of manufacture to capture data regarding media exposure (e.g., television viewing habits of person(s) in metered households) and to credit metered locations and/or devices with media presentation, exposure, and/or consumption are disclosed herein.

One example method of crediting media content as being presented by a media presentation device includes capturing ambient audio from the location of the media presentation device and, based on the ambient audio: 1) identifying information encoded in the ambient audio (e.g., watermarks,

3

codes, etc.), 2) generating signatures of the ambient audio for comparison with signatures of known media, and/or 3) determining whether the media presentation device is in an on state or an off state based on the ambient audio). In some examples, the recognition of embedded code(s) during a time period overrides a determination that the media presentation device is in an off state during the same time period, and enables the media presentation device to be credited with the media corresponding to the embedded code(s).

As used herein, media may refer to any type of audio and/or visual media including, but not limited to, television programs, advertisements, movies, video games, time-shifted programs, on-demand programs, and/or any other type of audio and/or video content and/or non-content media. Furthermore, the term media may refer to portions of and/or the entireties of such audio and/or visual media.

Example methods disclosed herein include obtaining ambient audio for a time period from a location including a media presentation device, detecting encoded information present in the ambient audio, crediting a first portion of the time period for the media presentation device to first media based on the encoded information, determining an on/off state of the media presentation device for a second portion of the time period different than the first portion based on the ambient audio, and crediting the second portion of the time period based on the on/off state of the media presentation device.

Some example methods further include computing a signature of the ambient audio corresponding to a third portion of the time period different from the first and second portions and crediting the third portion of the time period to the first media or to second media based on the signature. Some such example methods further include comparing the signature to a second signature, wherein crediting the third portion of the time period to the first media or to second media is based on the comparison. In some such examples, crediting the first portion based on the encoded information is performed before crediting the third portion based on the signature, and crediting the third portion is performed prior to crediting the second portion based on the on/off state of the media presentation device. In some such example methods, crediting the third portion based on the signature comprises overriding a determination that the media presentation device is in an off state during the third portion with a determination that the media presentation device is in an on state based on a comparison of the signature to a reference signature.

In some examples, crediting the second portion comprising assigning an off state to the second portion. In some example methods, crediting the first portion comprises overriding a determination that the media presentation device is in an off state during the first portion with a determination that the media presentation device is in an on state based on detecting the encoded information. In some example methods, obtaining the ambient audio comprises recording the ambient audio at the location.

In some examples, obtaining the ambient audio comprises receiving a data file including the ambient audio. In some example methods, detecting the encoded information comprises extracting a steganographically encoded watermark. In some examples, determining the on/off state of the audience measurement device is based only on the ambient audio.

Example apparatus disclosed herein include a code detector, an on/off detector, and a location creditor. The example code detector detects encoded information present in ambi-

4

ent audio collected from a monitored location. The example on/off detector determines a first portion of a time period during which a media presentation device in the monitored location is in an on state and determines a second portion of the time period during which the media presentation device is in an off state based on the ambient audio. The example location creditor credits a third portion of the time period for the media presentation device to first media based on the encoded information and credits a fourth portion of the time period different from the third portion based on the on state or the off state of the media presentation device during the fourth portion of the time period.

Some example apparatus further include a microphone to collect the ambient audio in the location including the media presentation device during a time period. Some example apparatus further include a network interface to receive the ambient audio via a network. Some example apparatus further include a signature generator to generate a signature of a portion of the ambient audio, the location creditor to credit a fifth portion of the time period based on the signature. In some such examples, the location creditor credits the third portion based on the encoded information prior to crediting the fifth portion based on the signature and credits the fifth portion prior to crediting the fourth portion based on the on state or the off state of the media presentation device.

Some other example methods disclosed herein include obtaining encoded information extracted from ambient audio, the ambient audio being recorded during a time period in a location including a media presentation device, crediting a first portion of the time period for the media presentation device to first media based on the encoded information, obtaining an on/off state of the media presentation device for a second portion of the time period different than the first portion, the on/off state being based on the ambient audio, and crediting the second portion of the time period based on the on/off state of the media presentation device.

In some examples, obtaining the encoded information includes receiving the encoded information in a data file from an audience measurement device located in the location. Some example methods further include obtaining a characterization of the ambient audio corresponding to a third portion of the time period different from the first and second portions, and crediting the third portion of the time period to the first media or to second media based on the signature. In some such example methods, obtaining the characterization comprises receiving a digital signature in the data file from an audience measurement device located in the location.

Some disclosed example apparatus include a processor and a memory storing computer readable instructions. When executed, the computer readable instructions cause the processor to access encoded information extracted from ambient audio, the ambient audio being recorded during a time period in a location including a media presentation device, credit a first portion of the time period for the media presentation device to first media based on the encoded information, access an on/off state of the media presentation device for a second portion of the time period different than the first portion, the on/off state being based on the ambient audio, and credit the second portion of the time period based on the on/off state of the media presentation device.

In some such example apparatus, the instructions are to cause the processor to access the encoded information in a data file received from an audience measurement device located in the location. In some examples, the instructions

5

further cause the processor to access a characterization of the ambient audio corresponding to a third portion of the time period different from the first and second portions and credit the third portion of the time period to the first media or to second media based on the signature. In some such examples, the instructions are to cause the processor to access a digital signature in a data file received from an audience measurement device located in the location.

Some disclosed example methods include obtaining ambient audio for a time period from a location including a media presentation device, computing a signature of the ambient audio, crediting a first portion of the time period for the media presentation device to first media based on the signature, determining an on/off state of the media presentation device for a second portion of the time period different than the first portion based on the ambient audio, and crediting the second portion of the time period based on the on/off state of the media presentation device. Some example methods further include comparing the signature to a second signature, wherein crediting the first portion of the time period to the first media is based on the comparison.

Some disclosed example apparatus include a signature generator, an on/off detector, and a location creditor. The example signature generator computes a signature of ambient audio collected from a monitored location. The on/off detector determines a first portion of a time period during which a media presentation device in the monitored location is in an on state and determines a second portion of the time period during which the media presentation device is in an off state based on the ambient audio. The example location creditor credits a third portion of the time period for the media presentation device to first media based on the signature and credits a fourth portion of the time period different from the third portion based on the on state or the off state of the media presentation device during the fourth portion of the time period. In some such example apparatus the location creditor compares the signature to a reference signature associated with the first media, wherein crediting the third portion of the time period is based on the comparison.

Some disclosed example methods include obtaining a characterization of ambient audio, the ambient audio being recorded during a time period in a location including a media presentation device, crediting a first portion of the time period for the media presentation device to first media based on the characterization, obtaining an on/off state of the media presentation device for a second portion of the time period different than the first portion, the on/off state being based on the ambient audio, and crediting the second portion of the time period based on the on/off state of the media presentation device. In some examples, obtaining the characterization includes accessing a digital signature in a data file received from the media presentation device. Some example methods further include comparing the characterization to a reference characterization, wherein crediting the first portion is based on the comparison.

Some disclosed example apparatus include a processor and a memory. The example memory stores computer readable instructions which, when executed, cause the processor to access a characterization of ambient audio, the ambient audio being recorded during a time period in a location including a media presentation device, credit a first portion of the time period for the media presentation device to first media based on the characterization, access an on/off state of the media presentation device for a second portion of the time period different than the first portion, the on/off state being based on the ambient audio, and credit the second

6

portion of the time period based on the on/off state of the media presentation device. In some examples, the instructions are to cause the processor to access the characterization from a data file received from the media presentation device. In some examples, the instructions are further to cause the processor to compare the characterization to a reference characterization, wherein crediting the first portion is based on the comparison.

Referring to FIG. 1, a media content provider **102** provides content to an audience via one or more information presentation devices, such as a set top box **104** and a television **106**. The components of the media presentation system may be coupled in any manner. In the illustrated example, the television **106** is positioned in a monitored area **120** located within a household occupied by one or more people, represented by a person **122**, some or all of whom have agreed to participate in an audience measurement research study. The monitored area **120** includes the area in which the television **106** is located and from which the one or more household member(s) **122** located in the monitored area **120** may view the television **106**.

The media content provider **102** may convey the media content to a metered household **120** via a cable network, a radio transmitter or one or more satellites. For example, the media content provider **102** may be a cable television provider distributing the television programs exclusively via a cable network or a satellite provider distributing media via satellite. The media content provider **102** may transmit media signals in any suitable format, such as a National Television Standards Committee (NTSC) television signal format, a high definition television (HDTV) signal format, an Association of Radio Industries and Businesses (ARIB) television signal format, etc.

In the example of FIG. 1, an audience measurement system **100** is used to collect audience measurement data concerning media activity associated with the metered household. A metered household may include one or more monitored areas **120**. To this end, the audience measurement system **100** includes an audience measurement device **108** to collect media presentation information associated with one or more media device(s) (e.g., the set top box **104** and the television **106**) in the monitored area **120**. In the example of FIG. 1, the audience measurement device **108** collects presentation information including ambient audio (e.g., via one or more microphones) and/or audience member identification (e.g., via audience member log-ins and/or audience member prompt suppression). The audio recorded via the microphone(s) of the example audience measurement device **108** may include ambient audio signals from the monitored media presentation device (e.g., the television **106**) and/or background noise from within the monitored area **120**. For example, the ambient audio may comprise audio signal(s) reflecting humanly audible and/or humanly inaudible sounds within the household recorded via microphone(s) coupled to or included in the audience measurement device **108**. Additionally or alternatively, the audience measurement device **108** may collect information including signals (e.g., infrared, radio frequency, etc.) generated by a remote control device **112**.

The example audience measurement device **108** of FIG. 1 provides the presentation information, which may include recorded or captured audio, detected codes associated with the ambient audio, digital signatures representative of the ambient audio, tuning and/or demographic information, etc. for evaluation in a back office **130**. In some examples, the audience measurement device **108** processes captured audio information to generate the presentation information. In

some other examples, the audience measurement device transmits the captured audio to the back office **130** for processing. In the example of FIG. **1**, the audience measurement device **108** transmits the presentation information via a data return path, such as cellular communications and/or wireless data communications, to the back office **130** for evaluation.

In the example of FIG. **1**, the information collected by the audience measurement device **108** is processed and/or stored in the back office **130** to produce ratings information. The example back office **130** of FIG. **1** includes a media creditor **132** to credit the television **106**, the monitored area **120**, and/or the person **122** with media presentation. The media creditor **132** and the audience measurement device **108** of FIG. **1** cooperate to identify codes or watermarks embedded in the ambient audio, generate signatures of the ambient audio, compare the generated signatures with reference signatures of known media, and/or determine whether the media presentation device is in an on state or an off state based on the ambient audio. Based on these factors, the example media creditor **132** credits the media presentation device **106**, the monitored area **120**, and/or the person **122** during the time period represented by the ambient audio with media.

FIG. **2** is a block diagram of an example audience measurement device **202** in communication with an example media creditor **204** to implement the audience measurement system **100** of FIG. **1**. The example audience measurement device **202** of FIG. **2** may be used to implement the audience measurement device **108** and the example media creditor **204** of FIG. **2** may be used to implement the media creditor **132** at the back office **130** of FIG. **1**.

The example audience measurement device **202** of FIG. **2** includes one or more microphones **206**, an automatic gain controller **210**, and a data file generator **212**. The example microphone **206** records ambient audio from a location within which the audience measurement device **202** is located. For example, the audience measurement device **202** may be configured such that the microphone **206** reliably captures audio output from a media presentation device (e.g., the presentation device **106** of FIG. **1**) to be monitored.

The example automatic gain controller (AGC) **210** of FIG. **2** receives the captured audio signals and applies an automatic gain algorithm to boost the signal levels based on the level (e.g., energy, amplitude) of the input signal. The example AGC **210** outputs the boosted signals and the amount of gain applied to the data file generator **212**. The example data file generator **212** of FIG. **2** generates a data file that includes the captured audio. In some examples, the data file further includes an indication of the gain applied by the AGC **210**. The example data file generator **212** includes time stamps corresponding to the captured audio and/or to the gain levels to enable correlation of the audio with particular times (e.g., to credit the media presentation device with media presentation for the proper time periods).

The example data file generator **212** outputs the data file to an input database **214** via a return path interface **216**. The example input database **214** of FIG. **2** obtains data files from multiple audience measurement devices for retrieval and processing by the media creditor **204**. The example return path interface **216** of FIG. **2** may include any type of communications interface, such as a cellular radio or wireless local area network (WLAN) radio. In the example of FIG. **2**, the return path interface **216** communicates with the input database **214** via a cellular data connection to an Internet protocol (IP) network to reduce or eliminate any

dependency of the return path to the media creditor **304** on WLAN infrastructure of the location being monitored.

The example media creditor **204** of FIG. **2** obtains the data file including captured ambient audio from the monitored area **120** (e.g., from the input database **214**, from the data file generator **212**) via a network interface **218** and credits the monitored location associated with the audience measurement device **202** (e.g., the monitored location **120** of FIG. **1**). To accurately credit the location based on the data file, the example media creditor **204** includes a code detector **220**, a signature generator **222**, an on/off detector **224**, and a location creditor **226**. The network interface **218** provides the received data file to each of the example code detector **220**, the example signature generator **222**, and the example on/off detector **224** to process the data file (e.g., process the audio).

The example code detector **220** of FIG. **2** detects embedded codes (e.g., steganographically embedded codes, watermarks, and/or other auxiliary data) present in the captured audio in the data file. The embedded codes may include information describing the media being presented, the channel being watched, and/or other audience measurement information. The example code detector **220** outputs the detected codes to the location creditor **226** to credit the media presentation device **106** with the media identified in the code(s).

The example code detector **220** may use any method(s) for detecting codes embedded in audio for audience measurement. In some cases, multiple embedded codes are present in a given block of audio and may be extracted using different techniques. Examples of techniques that may be used to extract embedded codes (e.g., watermarks) from the audio are described in U.S. patent application Ser. No. 12/249,619, assigned to The Nielsen Company (US), LLC, filed on Oct. 10, 2008; in U.S. patent application Ser. No. 12/361,991, assigned to The Nielsen Company (US), LLC, filed on Jan. 29, 2009; in U.S. Pat. No. 6,421,445, assigned to Arbitron Inc., issued on Jul. 16, 2002; and/or in U.S. Pat. No. 6,272,176, assigned to The Nielsen Company (US), LLC, issued on Aug. 7, 2001. The methods described in these patents and applications are merely examples, and any other method(s) may be used in addition and/or as an alternative to these methods.

The extracted embedded codes or watermarks may be identified using a code database **228** including a library of codes. In some examples, the codes in the code database **228** include information identifying media into which the codes have been inserted or embedded. The example location creditor **226** may determine whether an extracted code corresponds to a code that has been inserted into audio by querying the code database **228** for the extracted code. If the extracted code (or a code within an error range of the extracted code) is found, the example location creditor **226** may identify the extracted code as corresponding to the media of the code in the code database **228**.

The example signature generator **222** generates signatures of the captured audio in the data file. The generated signatures may be compared to reference signatures to match the audio to known media. The example media creditor **204** of FIG. **2** receives the reference signatures from a reference signature database **230**. Signature matching may be used to credit media presentation to portions of time in which embedded codes are not detected and/or are not recognizable.

The example signature generator **222** may use any method(s) for characterizing audio (e.g., generating signatures of audio) and/or comparing generated signatures to

reference signatures. In some cases, multiple signatures using different techniques. Examples of techniques that may be used to extract embedded codes (e.g., watermarks) from the audio are described in U.S. Pat. No. 8,060,372, assigned to The Nielsen Company (US), LLC, issued on Nov. 15, 2011; in U.S. patent application Ser. No. 12/110,951, assigned to The Nielsen Company (US), LLC, filed on Apr. 28, 2008; and/or U.S. patent application Ser. No. 12/266,380, assigned to The Nielsen Company (US), LLC, filed on Nov. 6, 2008. The methods described in these patents and applications are merely examples, and any other method(s) to generate signatures may be used in addition and/or as an alternative to these methods to implement the signature generator 222.

The example on/off detector 224 of FIG. 2 determines when the media presentation device 106 is in an on state and/or when the media presentation device 106 is in an off state during the time period represented by the audio in the data file. To determine the on state(s) and/or the off state(s), the example on/off detector 224 uses, for example, fuzzy logic, rules, or heuristics to make inferences regarding the on/off state of the media presentation device 106. In some examples, the on/off detector 224 determines the on/off state of the media presentation device 106 based only on the captured audio, where processing of the audio (e.g., gain levels, statistics of the audio) are considered to be based on the captured audio. For example, the on/off detector 224 may determine, for a given portion of the time period, whether the media presentation device 106 is in an on state or an off state based on the gain level applied by the AGC 210 and/or based on processing the audio, without measuring power drawn by the media presentation device 106. An example method to implement the on/off detector 224 of FIG. 2 is described in U.S. Pat. No. 8,180,712, assigned to The Nielsen Company (US), LLC, issued on May 15, 2012. However, other methods of audio-based on/off detection may additionally or alternatively be used.

The example location creditor 226 of FIG. 2 receives extracted codes (e.g., from the code detector 220), generated signatures representative of the audio (e.g., from the signature generator 222), and/or determinations of the on state periods and/or the off state periods of the media presentation device 106 (e.g., from the on/off detector 224). Based on the received codes, signatures, and determinations, the example location creditor 226 credits the media presentation device 106 with the appropriate media presentations during the time period represented by the data file.

In the example of FIG. 2, the location creditor 226 overrides determinations of an off state by the on/off detector 224 when extracted codes and/or matching signatures from the audio in the data file indicates that media being presented by the media presentation device 106 during a corresponding time. For example, the location creditor 226 may credit the time periods for which a code is extracted and for which matching signatures are found prior to crediting time periods based on on/off detection information.

The example location creditor 226 outputs the crediting information for the time period represented by the captured audio. The crediting information may be stored and/or aggregated with crediting information for other time periods and/or other audience measurement devices to, for example, generate ratings information.

FIG. 3 is a block diagram of another example audience measurement device 302 in communication with another example media creditor 304 to implement the audience measurement system 100 of FIG. 1. The example audience measurement device 302 of FIG. 3 may be used to imple-

ment the audience measurement device 108 and the example media creditor 304 of FIG. 3 may be used to implement the media creditor 132 at the back office 130 of FIG. 1.

In contrast to the example audience measurement device 202 of FIG. 2, the example audience measurement device 302 of FIG. 3 generates a data file including extracted codes, generated signatures, and/or on/off detection information. The example media creditor 304 may then perform the crediting of the location based on the information received via the data file.

The example audience measurement device 302 of FIG. 3 includes one or more microphones 206, an AGC 210, a data file generator 212, a return path interface 216, a code detector 220, a signature generator 222, and an on/off detector 224. Because many of the elements of FIG. 3 are similar to elements in the example of FIG. 2, like reference numbers are used to refer to like elements. This numbering convention is employed throughout this description to reduce redundant description.

The example microphone 206 of FIG. 3 captures ambient audio from a media presentation device to be measured (e.g., the media presentation device 106 of FIG. 1). The microphone 206 outputs an electrical signal representative of the audio to the AGC 210, which applies a gain to the electrical signal based on the level (e.g., the energy, the amplitude, etc.) of the captured audio. In contrast to the AGC 210 of FIG. 2, which outputs the amplified signal and the gain level to the data file generator 212, the example AGC 210 of FIG. 3 outputs the audio and/or the gain level to the code detector 220, the signature generator 222, and the on/off detector 224. In some examples, the AGC 210 also provides the amplified signal to the data file generator 212 for inclusion (e.g., storage) in a data file generated by the data file generator 212.

The example data file generator 212 of FIG. 3 receives outputs from the example code detector 220, the example signature generator 222, and the example on/off detector 224. For example, the code detector 220 of FIG. 3 extracts codes embedded in the captured audio and provides the codes to the example data file generator 212. The example signature generator 222 of FIG. 3 generates signatures representative of the captured audio and provides the generated signatures to the example data file generator 212. The example on/off detector 224 of FIG. 3 determines periods of time during which the media presentation device 106 is in an on state and periods of time during which the media presentation device 106 is in an off state, and provides the determinations and/or the time periods to the example data file generator 212.

The example data file generator 212 of FIG. 3 generates a data file including extracted codes or watermarks, generated signatures, and/or on state and/or off state determinations for the media presentation device 106. As mentioned above, the example data file generator 212 may further include the captured audio and/or the gain levels. The audience measurement device 302 transmits the data file via the return path interface 216 to an input database 214, which stores the data file for retrieval by the media creditor 304.

The example media creditor 304 of FIG. 3 includes a network interface 218 and a location creditor 226. The example network interface 218 receives the data file from the input database 214 and/or from the return path interface 216. Based on the data file, the location creditor 226 credits the media presentation device 106 with media presentations based on the extracted codes, the generated signatures, and/or the on/off state determinations. In the example of FIG. 3, the location creditor 226 compares the generated

## 11

signatures in the data file to signatures from a reference signature database 230 to identify media represented by the generated signatures. The example location creditor 226 outputs the crediting of the media presentation device 106 to, for example, generate television ratings information.

In the example of FIG. 3, the location creditor 226 first applies extracted codes (e.g., watermarks) in the data file to credit the media presentation device 106. For portions of a time period represented by the data file in which codes are not recognized, the example location creditor 226 of FIG. 3 determines whether the signatures corresponding to those portions match reference signatures. The example location creditor 226 of FIG. 3 credits the media presentation device 106 for the portions of the time period based on matching signatures. For portions of the time period that cannot be credited based on either codes or signatures (e.g., the remaining portions of the time period), the example location creditor 226 credits the media presentation device 106 using the determinations of the on states of the media presentation device 106 and the off states of the media presentation device 106.

While example manners of implementing the audience measurement system 100 of FIG. 1 have been illustrated in FIGS. 2 and 3, one or more of the elements, processes and/or devices illustrated in FIGS. 2 and/or 3 may be combined, divided, re-arranged, omitted, eliminated and/or implemented in any other way. Further, the example AGC 210, the example data file generator 212, the example input database 214, the example return path interface 216, the example network interface 218, the example code detector 220, the example signature generator 222, the example on/off detector 224, the example location creditor 226, the example reference signature database 230 and/or, more generally, the example audience measurement device 108, 202, 302 and/or the example media creditor 132, 204, 304 of FIGS. 1-3 may be implemented by hardware, software, firmware and/or any combination of hardware, software and/or firmware. Thus, for example, any of the example AGC 210, the example data file generator 212, the example input database 214, the example return path interface 216, the example network interface 218, the example code detector 220, the example signature generator 222, the example on/off detector 224, the example location creditor 226, the example reference signature database 230 and/or, more generally, the example audience measurement device 108, 202, 302 and/or the example media creditor 132, 204, 304 of FIGS. 1-3 could be implemented by one or more circuit(s), programmable processor(s), application specific integrated circuit(s) (ASIC(s)), programmable logic device(s) (PLD(s)) and/or field programmable logic device(s) (FPLD(s)), etc.

When any of the apparatus or system claims of this patent are read to cover a purely software and/or firmware implementation, at least one of the example AGC 210, the example data file generator 212, the example input database 214, the example return path interface 216, the example network interface 218, the example code detector 220, the example signature generator 222, the example on/off detector 224, the example location creditor 226, the example reference signature database 230 of FIGS. 2 and/or 3 are hereby expressly defined to include a tangible computer readable medium such as a memory, DVD, CD, Blu-ray, etc. storing the software and/or firmware. Further still, the example audience measurement device 202, 302 and/or the example media creditor 204, 304 of FIGS. 2 and/or 3 may include one or more elements, processes and/or devices in addition to, or instead of, those illustrated in FIGS. 2 and/or

## 12

3, and/or may include more than one of any or all of the illustrated elements, processes and devices.

FIG. 4 illustrates a time period 400 representative of crediting media presentations and/or non-presentations to a media presentation device during in an example process to perform crediting. The example process of FIG. 4 includes a set of credited time periods 402-410 that may be performed using the audience measurement device 108, 202, 302 and/or the media creditor 132, 204, 304 of FIGS. 1-3. The example credited time periods 402-410 correspond to the same time period 400, which represents captured or recorded audio in a data file to be processed. The example time period 400 and the portions of the time period 400 discussed below are illustrative, and are not necessarily to scale. In the example of FIG. 4, different crosshatching is used to illustrate portions of the time period 400 that are credited using different techniques and do not necessarily represent different media.

In the example credited time period 402 of FIG. 4 the data file is yet to be processed and no part of the time period 400 has been credited. In the example credited time period 404, the example code extractor 220 and/or the example location creditor 226 of FIGS. 2 and/or 3 determine, based on the data file, that embedded codes were present in the captured audio during portions 414, 416, 418 of the time period 400. Accordingly, the example location creditor 226 credits the portions 414-418 with respective media presentations, while the remainder of the time period 400 in the credited time period 404 are not credited.

In the example credited time period 406 of FIG. 4, the example signature generator 222 and/or the example location creditor 226 of FIGS. 2 and/or 3 determine, based on generated signatures in the data file, that a portion 420 of the time period 400 corresponds to a media presentation. The example location creditor 226 of FIGS. 2 and/or 3 credits the portion 420 with media presentation (e.g., based on the reference signature to which the generated signature is matched). The remaining portions of the time period 400 that have not been credited based on codes or signature matching remain not credited at credited time period 406.

In the example credited time period 408, the example on/off detector 224 and/or the example location creditor 226 of FIGS. 2 and/or 3 determine, based on generated signatures in the data file, that portions 422, 424 of the time period 400 are to be credited as in an on state (e.g., presenting media) and portions 426, 428, 430 of the time period 400 are to be credited as in an off state (e.g., not presenting media). Therefore, after the example credited time period 408, the media presentation device 106 has been credited for the entire example time period 400 (e.g., based on particular media, not based on particular media, and/or in an off state).

In the example credited time period 410, the example location creditor 226 of FIGS. 2 and/or 3 determines the media with which the media presentation device 106 is to be credited during the time period 400. For example, while the portions 422, 424 in the credited time period 408 are initially credited as in an on state (and, therefore, presumably presenting media), the example location creditor 226 may determine the media being presented during the portions based on, for example, continuity of audio with portions 414, 416, and/or 420 adjacent to the portions 422 and/or 424. In some examples, if the portions 422 and/or 424 are sufficiently brief and the portions adjacent the portions 422, 424 represent identical media, the location creditor 226 may assume that the portions 422 and/or 424 represent the same media as the adjacent portion(s). Any other appropriate

13

assumptions may be used to credit the portions **422**, **424** that correspond to an on state of the media presentation device **106**.

In the example credited time period **410** of FIG. **4**, the location creditor **226** credits contiguous portion **430**, contiguous portion **432**, and contiguous portion **434** with different media. The example location creditor **226** credits the portions **436**, **438**, and **440** with an off state representative of media not being presented by the media presentation device **106**.

In some other examples, the audio may be provided for the portions **422**, **424** for further analysis to determine the media being presented during the portions **422**, **424**. Such analysis may include applying additional signaturing techniques and performing comparisons of the signatures and/or enabling a human to listen to the audio to determine whether the audio corresponds to the same media as adjacent portions **414**, **416**, and/or **420**.

While the example credited time periods **402-410** of FIG. **4** are shown in a particular order, other sequences of crediting may be used. For example, the location creditor **226** of FIGS. **2** and/or **3** may credit the on states and/or the off states of the media presentation device **106** and subsequently override the on states and/or the off states with crediting of media based on extracted codes and/or signaturing.

Flowcharts representative of example machine readable instructions for implementing the example AGC **210**, the example data file generator **212**, the example input database **214**, the example return path interface **216**, the example network interface **218**, the example code detector **220**, the example signature generator **222**, the example on/off detector **224**, the example location creditor **226**, the example reference signature database **230** and/or, more generally, the example audience measurement device **108**, **202**, **302** and/or the example media creditor **132**, **204**, **304** of FIGS. **1-3** are shown in FIGS. **5-7**. In this example, the machine readable instructions comprise program(s) for execution by a processor such as the processor **812** shown in the example processor platform **800** discussed below in connection with FIG. **8**. The program(s) may be embodied in software stored on a tangible computer readable medium such as a CD-ROM, a floppy disk, a hard drive, a digital versatile disk (DVD), a Blu-ray disk, or a memory associated with the processor **812**, but the entire program(s) and/or parts thereof could alternatively be executed by a device other than the processor **812** and/or embodied in firmware or dedicated hardware. Further, although the example program is described with reference to the flowcharts illustrated in FIGS. **5-7** many other methods of implementing the example AGC **210**, the example data file generator **212**, the example input database **214**, the example return path interface **216**, the example network interface **218**, the example code detector **220**, the example signature generator **222**, the example on/off detector **224**, the example location creditor **226**, the example reference signature database **230** and/or, more generally, the example audience measurement device **108**, **202**, **302** and/or the example media creditor **132**, **204**, **304** of FIGS. **1-3** may alternatively be used. For example, the order of execution of the blocks may be changed, and/or some of the blocks described may be changed, eliminated, or combined.

The example instructions **500-700** of FIGS. **5**, **6**, and/or **7** may be implemented using coded instructions (e.g., computer readable instructions) stored on a tangible computer readable medium such as a hard disk drive, a flash memory, a read-only memory (ROM), a compact disk (CD), a digital

14

versatile disk (DVD), a cache, a random-access memory (RAM) and/or any other storage medium in which information is stored for any duration (e.g., for extended time periods, permanently, brief instances, for temporarily buffering, and/or for caching of the information). As used herein, the term tangible computer readable storage medium is expressly defined to include any type of computer readable storage device or storage disc (e.g., a magnetic storage disc, an optical storage disc) and to exclude propagating signals. Additionally or alternatively, the example processes of FIGS. **5**, **6**, and/or **7** may be implemented using coded instructions (e.g., computer readable instructions) stored on a non-transitory computer readable medium such as a hard disk drive, a flash memory, a read-only memory, a compact disk, a digital versatile disk, a cache, a random-access memory and/or any other storage media in which information is stored for any duration (e.g., for extended time periods, permanently, brief instances, for temporarily buffering, and/or for caching of the information). As used herein, the term non-transitory computer readable medium is expressly defined to include any type of computer readable storage device or storage disc (e.g., a magnetic storage disc, an optical storage disc) and to exclude propagating signals. As used herein, when the phrase "at least" is used as the transition term in a preamble of a claim, it is open-ended in the same manner as the term "comprising" is open ended. Thus, a claim using "at least" as the transition term in its preamble may include elements in addition to those expressly recited in the claim.

FIG. **5** is a flowchart representative of example machine readable instructions **500** that may be executed to implement the example audience measurement devices **108**, **202**, **302** of FIGS. **1-3**. The example instructions **500** may be executed to generate a data file for transmission via a return path to the example media creditors **116**, **204**, **304** of FIGS. **1-3**. The instructions **500** of FIG. **5** will be described, by way of example, with reference to the example audience measurement device **302** of FIG. **3**.

The example audience measurement device **302** initializes (block **502**). For example, the audience measurement device **108** may determine a number and/or type of microphones **206**, **208** for capturing audio and determine a reference time signal (e.g., from a cellular data connection via the return path interface **216**). The example audience measurement device **302** is calibrated (block **504**). For example, the audience measurement device **302** may be calibrated to an ambient audio level in a location in which the audience measurement device **302** is placed and/or may be calibrated to an audio level and/or audio range of a media presentation device **106** to be monitored via the audience measurement device **302**. In some examples, calibration improves the accuracy of on/off state determinations.

The example audience measurement device **302** captures (e.g., records) ambient audio in the location (block **506**). For example, the audience measurement device **302** captures audio output from the media presentation device **106** being monitored when the media presentation device **106** is playing audio.

The example audience measurement device **302** determines whether to process the captured audio (block **508**). For example, the audience measurement device **302** may be enabled to extract codes or watermarks embedded in the captured audio, generate digital signatures representative of the captured audio, and/or determine whether the media presentation device **106** is in an on state or an off state based on the captured audio. If the audience measurement device **302** is to process the captured audio (block **508**), the

15

example audience measurement device **302** proceeds to process the audio (block **510**). Example instructions to implement block **510** are described below with reference to FIG. 7.

After processing the audio (block **510**), or if the audience measurement device **302** is to not process the audio (block **508**), the example audience measurement device **302** determines whether to include the captured audio in the data file (block **512**). If the audience measurement device **302** is to include the captured audio in the data file (block **512**), the example audience measurement device **302** stores the captured audio in the data file (block **514**). In some examples, the audience measurement device **302** includes the captured audio in the data file (block **514**) when the audio is not processed by the audience measurement device **302** (block **508**). In some examples, the audience measurement device **302** does not include the captured audio in the data file when the audience measurement device **302** processes the audio in the data file (e.g., includes extracted code(s), generated signature(s), and/or on/off determinations in the data file in block **510**).

After storing the captured audio in the data file (block **514**), or if the captured audio is not to be included (block **512**), the example audience measurement device **302** determines whether the data file is to be transmitted (block **516**). For example, the audience measurement device **302** may transmit the data file (e.g., from the data file generator **212** via the return path interface **216** of FIGS. 2 and/or 3) periodically, aperiodically, at particular times, in response to an event or condition (e.g., a local memory is filled), on request, and/or based on any other criteria. If the audience measurement device **302** is to not transmit the data file (block **516**) (e.g., a measurement period has not yet elapsed), control returns to block **506** to continue capturing ambient audio.

When the audience measurement device **302** is to transmit the data file (block **516**) (e.g., a time period has elapsed), the example data file generator **212** generates the data file corresponding to a time period (block **518**). The generated data file may include the captured audio and/or any data resulting from processing the audio. The example data file generator **212** transmits the data file via the return path interface **216** (block **520**). For example, the return path interface **216** may establish a cellular data connection to transmit the data file to the input database **214** and/or to the media creditor **304** of FIG. 3. The example instructions **500** may then end and/or iterate to capture audio for a subsequent measurement period. In some examples, iterating the instructions **500** may result in omitting blocks **502** and/or **504** for the subsequent iterations.

FIG. 6 is a flowchart representative of example machine readable instructions **600** that may be executed to implement the example media creditor **132**, **204**, **304** of FIGS. 1-3. The example instructions **600** may be executed to credit a media presentation device based on a data file. The instructions **600** of FIG. 6 will be described, by way of example, with reference to the example media creditor **204** of FIG. 2.

The example media creditor **204** receives a data file (e.g., from the audience measurement device **202** and/or the input database **214** of FIG. 2) (block **602**). The example data file may include captured audio, gain levels for the AGC **210**, codes or watermarks extracted from the audio, signatures representative of the audio, on/off determinations, time stamps, and/or identification data for the monitored location associated with the audience measurement device **202**.

The example media creditor **204** (e.g., via the location creditor **226**) determines a time period and an audience

16

measurement device represented by the data file (block **604**). For example, the location creditor **226** may determine that the data file corresponds to a predetermined time period (e.g., a particular day, a particular week, etc.) and/or may determine the time period based on a range of time stamps in the data file. The example location creditor **226** of FIG. 3 may determine the audience measurement device based on an identification of the audience measurement device **202** and/or an identification of the media presentation device **106** included in the data file.

The example location creditor **226** determines whether the audio in the data file is to be processed (block **606**). In examples in which the audience measurement device **202** does not process the audio, the example location creditor **226** may determine that the audio is to be processed. For example, the location creditor **226** may determine whether signatures and/or on/off determinations are present or omitted from the data file, which may indicate whether the audience measurement device **202** performed processing on the captured audio.

For example, the media creditor **204** may be enabled to extract codes or watermarks embedded in the captured audio (e.g., via the code extractor **220** of FIG. 2), generate digital signatures representative of the captured audio (e.g., via the signature generator **222** of FIG. 2), and/or determine whether the media presentation device **106** is in an on state or an off state based on the captured audio (e.g., via the on/off detector **224** of FIG. 2). If the audience measurement device **302** is to process the captured audio (block **606**), the example audience measurement device **302** proceeds to process the audio (block **608**). Example instructions to implement block **608** are described below with reference to FIG. 7.

After processing the audio (block **608**), or if the media creditor **204** is to not process the audio (block **606**), the example media creditor **204** determines (e.g., via the location creditor **226**) whether extracted code(s) are present (block **610**). The location creditor **226** may determine whether code(s) are present in the data file and/or from processing the audio. If extracted codes are present (block **610**), the example location creditor **226** credits the respective portion(s) of the time period represented by the data file based on the extracted code(s) (block **612**). Crediting the portions of the time period may include, for example, associating media identified via the extracted codes with the media presentation device **106** for the portions of the time period.

After crediting based on the extracted code(s) (block **612**), or if no extracted codes are present (block **610**), the example location creditor **226** determines whether any signatures of the audio are present (block **614**). The location creditor **226** may determine whether signature(s) are present in the data file and/or from processing the audio. If signature(s) are present (block **614**), the example location creditor **226** compares the signature(s) to reference signature(s) (block **616**). The example location creditor **226** credits portion(s) of the time period represented by the data file based on the comparison(s) of the signature(s) to the reference signature(s) (block **618**). For example, if a generated signature is considered to match a reference signature, the example location creditor **226** credits the portion of the time period associated with the generated signature (e.g., credits the media presentation device **106** with the media corresponding to the matched reference signature).

After crediting based on the comparison(s) of the signature(s) to reference signature(s) (block **618**), or if there are no signatures present (block **614**), the example location

17

creditor **226** credits portion(s) of the time period based on determinations of on states of the media presentation device **106** and/or off states of the media presentation device **106** (block **620**). For example, the location creditor **226** may use the on/off determinations to credit the portion(s) of the time period that were not credited using codes (block **612**) and/or signatures (block **618**). In some examples, the location creditor **226** further credits media to the media presentation device **106** for the portion(s) of the time period during which the media presentation device **106** is determined to be on.

The example location creditor **226** outputs the crediting of the media presentation device **106** for the time period represented by the data file (block **622**). The crediting of the media presentation device **106** may be used to, for example, determine demographic information and/or generate television ratings information.

FIG. 7 is a flowchart representative of example machine readable instructions **700** that may be executed to implement the example media creditor **132**, **204**, **304** of FIGS. 1-3 and/or the example audience measurement device **108**, **202**, **302** of FIGS. 1-3 to process captured audio. The instructions **700** of FIG. 7 will be described, by way of example, with reference to the example media creditor **204** of FIG. 2.

The example instructions **700** of FIG. 7 may be executed in response to an audience measurement device (e.g., the audience measurement device **108**, **202**, **302** of FIGS. 1-3) and/or a media creditor (e.g., media creditor **132**, **204**, **304** of FIGS. 1-3). The example media creditor **204** (e.g., via the code extractor **220** of FIG. 2) detects code(s) present in the captured audio (block **702**). The example code extractor **220** may use any method of detecting and/or extracting embedded codes, watermarks, and/or any other type of auxiliary information from the audio. The example code extractor **220** determines whether any codes are detected (block **704**) and, if so, stores the detected code(s) (block **706**). For example, the code extractor **220** may store the codes in association with the data file for later crediting of the time period represented by the data file. The example code extractor **220** of FIG. 2 may further store a timestamp corresponding to a time or a range of time represented by the data file at which each particular code was detected.

After storing the detected code(s) (block **706**), or if no codes are detected in the audio (block **704**), the example media creditor **204** (e.g., via the signature generator **222** of FIG. 2) generates signature(s) of the captured audio (block **708**). The example signature generator **222** may use any method of digitally characterizing the captured audio. In some examples, the signature generator **222** generates multiple signatures to characterize the time period of the data file. In some examples, the signature generator **222** also generates multiple signatures of identical or overlapping portions of the time period to perform one or more characterization or signaturing methods. The example signature generator **222** stores the generated signature(s) (block **710**). For example, the signature generator **222** may store the generated signature(s) in association with the data file for later crediting of the time period represented by the data file. The example signature generator **222** of FIG. 2 may further store timestamp(s) corresponding to time(s) and/or range(s) of time represented by the data file that are characterized by each of the generated signature(s).

The example media creditor **204** (e.g., via the on/off detector **224**) determines whether the captured audio represents an on state or an off state of the media presentation device **106** for the time periods represented by the data file (block **712**). For example, the on/off detector **224** may analyze portions of the audio and/or other data, such as gain

18

levels applied to captured audio by the AGC **210**, to determine at what times the media presentation device **106** was in an on state and at what times the media presentation device **106** was in an off state during the time period represented by the data file. The example on/off detector **224** stores the on/off determination(s) (block **714**). For example, the on/off detector **224** may store the on/off determinations in association with the data file for later crediting of the time period represented by the data file.

The example instructions **700** may then end and control returns to block **512** of FIG. 5 or block **610** of FIG. 6.

FIG. 8 is a block diagram of an example processor platform **800** capable of executing the instructions of FIGS. 5-7 to implement the example audience measurement device **108**, **202**, **302** and/or the example media creditor **132**, **204**, **304** of FIGS. 1, 2, and/or 3. The processor platform **800** can be, for example, a server, a personal computer, or any other type of computing device.

The processor platform **800** of FIG. 8 includes a processor **812**. For example, the processor **812** can be implemented by one or more microprocessors or controllers from any desired family or manufacturer.

The processor **812** includes a local memory **813** (e.g., a cache) and is in communication with a main memory including a volatile memory **814** and a non-volatile memory **816** via a bus **818**. The volatile memory **814** may be implemented by Synchronous Dynamic Random Access Memory (SDRAM), Dynamic Random Access Memory (DRAM), RAMBUS Dynamic Random Access Memory (RDRAM) and/or any other type of random access memory device. The non-volatile memory **816** may be implemented by flash memory and/or any other desired type of memory device. Access to the main memory **814**, **816** is controlled by a memory controller.

The processor platform **800** also includes an interface circuit **820**. The interface circuit **820** may be implemented by any type of interface standard, such as an Ethernet interface, a universal serial bus (USB), and/or a PCI express interface.

One or more input devices **822** are connected to the interface circuit **820**. The input device(s) **822** permit a user to enter data and commands into the processor **812**. The input device(s) can be implemented by, for example, a keyboard, a mouse, a touchscreen, a track-pad, a trackball, isopoint and/or a voice recognition system.

One or more output devices **824** are also connected to the interface circuit **820**. The output devices **824** can be implemented, for example, by display devices (e.g., a liquid crystal display, a cathode ray tube display (CRT), a printer and/or speakers). The interface circuit **820**, thus, typically includes a graphics driver card.

The interface circuit **820** also includes a communication device such as a modem or network interface card to facilitate exchange of data with external computers via a network **826** (e.g., an Ethernet connection, a digital subscriber line (DSL), a telephone line, coaxial cable, a cellular telephone system, etc.). The example interface circuit **820** may implement the return path interface **216** and/or the network interface **218** of FIGS. 2 and/or 3.

The processor platform **800** also includes one or more mass storage devices **828** for storing software and data. Examples of such mass storage devices **828** include floppy disk drives, hard drive disks, compact disk drives and digital versatile disk (DVD) drives. The mass storage device **828** may implement the input database **214** of FIGS. 2 and/or 3.

The coded instructions **832** of FIGS. 5-7 may be stored in the mass storage device **828**, in the volatile memory **814**, in

19

the non-volatile memory 816, and/or on a removable storage medium such as a CD or DVD.

Although certain example methods, apparatus and articles of manufacture have been described herein, the scope of coverage of this patent is not limited thereto. On the contrary, this patent covers all methods, apparatus and articles of manufacture fairly falling within the scope of the appended claims either literally or under the doctrine of equivalents.

What is claimed is:

1. A method, comprising: obtaining, with a processor, ambient audio for a time period from a monitored location including a media presentation device;

without measuring power drawn by the media presentation device, determining, with the processor, the media presentation device was in an off state during the time period based on a gain level applied by an automatic gain controller (AGC) at the monitored location during the time period;

identifying information encoded in the ambient audio; generating a signature of the ambient audio for comparison with signatures of known media;

determining whether the media presentation device is in an on state or an off state based on information encoded in the ambient audio or the signature; and crediting a first portion of the time period for the media presentation device to first media based on the encoded information or the signature, wherein the crediting of the first portion includes overriding a determination that the media presentation device was in the off state during the first portion with a determination that the media presentation device was in the on state based on the identifying of the encoded information or the signature.

2. A method as defined in claim 1, further including comparing the signature to the reference signatures of the known media, wherein the crediting of the media presentation device with the presenting of the media is based on the comparison.

3. A method, comprising:

obtaining, with a processor at a back office, a file containing ambient audio collected for a time period by an audience measurement device monitoring a media presentation device at a monitored location remote from the back office, the file identifying a gain level applied to collect the ambient audio;

determining, with the processor, the media presentation device was in an off state during the time period based on the gain level;

analyzing, with the processor, the ambient audio for encoded information;

at least when the encoded information is not present in the ambient audio, generating, with the processor, a signature based on the ambient audio and attempting to match the signature to a set of reference signatures;

if either the encoded information is present in the ambient audio or the signature matches at least one of the reference signatures:

overriding, with the processor, the determination that the media presentation device was in the off state; and

20

crediting, with the processor, the media presentation device with presenting media corresponding to at least one of the encoded information or the signature during the time period.

4. A method as defined in claim 1, wherein the obtaining of the ambient audio includes recording the ambient audio at the monitored location.

5. A method as defined in claim 1, wherein the obtaining of the ambient audio includes receiving a data file including the ambient audio.

6. A method as defined in claim 1, wherein the detecting of the encoded information includes extracting a steganographically encoded watermark.

7. A method as defined in claim 1, wherein the overriding of the determination that the media presentation device was in the off state is based only on the ambient audio.

8. A tangible computer readable storage medium comprising computer readable instructions which, when executed, cause a processor to at least:

access ambient audio collected for a time period at a monitored location including a media presentation device;

without measuring power drawn by the media presentation device, determine the media presentation device was in an off state during a time period based on a gain level applied by an automatic gain controller (AGC) at the monitored location during the time period; identify information encoded in the ambient audio; generate a signature of the ambient audio for comparison with signatures of known media;

determine whether the media presentation device is in an on state or an off state based on information encoded in the ambient audio or the signature; and

credit a first portion of the time period for the media presentation device to first media based on the encoded information or the signature, the crediting of the first portion including overriding a determination that the media presentation device was in the off state during the first portion with a determination that the media presentation device was in the on state based on the identifying of the encoded information or the signature.

9. A storage medium as defined in claim 8, wherein the instructions further cause the processor to compare the signature to the signatures of known media, and the instructions cause the processor to credit the media presentation device with presenting the media based on the comparison.

10. A storage medium as defined in claim 8, wherein the ambient audio is recorded at the monitored location.

11. A storage medium as defined in claim 8, wherein the ambient audio is stored in a data file.

12. A storage medium as defined in claim 8, wherein the instructions cause the processor to detect the encoded information by extracting a steganographically encoded watermark.

13. A storage medium as defined in claim 8, wherein the instructions cause the processor to override the determination that the media presentation device is in the off state is based only on the ambient audio.

14. An apparatus, comprising: a code detector to detect encoded information present in ambient audio obtained for a time period from a media presentation device; a signature generator to compute a signature of the ambient audio for comparison with signatures of known media; an on/off detector to determine an on/off state of the media presentation device based on a gain level applied by an automatic gain controller to collect the ambient audio, the on/off detector to determine an on/off state of the media presenta-

## 21

tion device based on information encoded in the ambient audio or the signature; and a location creditor to credit a first portion of the time period for the media presentation device to first media based on at least one of the encoded information or the signature, the location creditor to credit the first portion by overriding a determination that the media presentation device was in the off state during the first portion with a determination that the media presentation device was in the on state based on the identifying of the encoded information or the signature.

15 15. An apparatus as defined in claim 14, wherein the location creditor is to compare the signature to the signatures of known media and to credit the media based on the comparison.

16. An apparatus as defined in claim 14, wherein the ambient audio is recorded at a monitored location.

17. An apparatus as defined in claim 14, wherein the code detector is to receive a data file including the ambient audio.

18. An apparatus as defined in claim 14, wherein the code detector is to detect the encoded information by extracting a steganographically encoded watermark.

19. An apparatus as defined in claim 14, wherein the location creditor is to override the determination by the

## 22

on/off detector that the media presentation was in the off state based only on the ambient audio.

20. An apparatus, comprising: a code detector to detect encoded information present in ambient audio obtained from a media presentation device; a signature generator to compute a signature of the ambient audio; an on/off detector to determine an on/off state of the media presentation device based on a gain level applied by an automatic gain controller to collect the ambient audio; and a location creditor to credit the media presentation device with presenting media when at least one of the code detector detects the encoded information and a comparison of the signature with signatures of known media results in a match, irrespective of the determination of the on/off state by the on/off detector, the location creditor to not credit the media presentation device with presenting media when the code detector does not detect the encoded information and the signature does not match any of the signatures of the known media and the on/off detector determines the media presentation device is in the off state.
